

The concept of the internet began in the late 1960s with the creation of ARPANET, a project funded by the United States Department of Defense's Advanced Research Projects Agency (DARPA). The primary goal was to build a robust, fault-tolerant communication network that could survive partial node destruction. In 1969, the first successful message, the word "login," was attempted from UCLA to Stanford University, though the system crashed after the first two letters. Over the next two decades, technologies evolved significantly. In 1983, ARPANET adopted the TCP/IP networking protocol, establishing the technical foundation for the modern internet. The network expanded internationally, connecting universities and research labs. The ultimate breakthrough for public utility came in 1989 when British scientist Tim Berners-Lee invented the World Wide Web while working at CERN. He introduced HTML, HTTP, and the first web browsers, transforming a data-sharing network for scientists into the global information ecosystem used by billions today.
